OpenSpec Plan: Template Disk Sizing Fix

Change: **template-disk-sizing** | Repo: **github.com/mkdev-ai/devsy-proxmox-provider** | Branch: **feature/template-disk-sizing**

Problem

The template base disk the workspace is built from is too small. **scripts/setup.sh** creates the cloud-init template from the Ubuntu cloud image with no size argument, so the template lands at the image default — **3584 M (~3.5 GB)**, as the Proxmox web UI screenshot of **devsy-ubuntu-24-04** (ID 9000) confirms (virtio0 = 3584 M). The provider's **VM_DISK_SIZE** option only resizes the *clone* after cloning, and did so against a hard-coded "expect ~17 GB template" assumption, so it could never produce the requested capacity. The result: **fatal: write error: No space left on device** mid *git clone* / docker pull after VM start.

Root cause (verified)

• The template base disk is the Ubuntu cloud-image default (~3.5 GB), not the requested 50 GB.

• VM_DISK_SIZE applies to the clone, only after cloning, and used a brittle +33G calc from a guessed 17 GB template base.

• The clone's repo fetch then fails on the small disk before the requested 50 GB is ever available.

• The agent's local data root is a separate filesystem (DEVSY_HOME) and is unrelated to the Proxmox template.

Design decisions

1. Size the template at creation time: pass --size to qm importdisk (setup.sh --template-disk-size, MiB, default 3584).

2. Resize the clone to exactly VM_DISK_SIZE, computed from the real template base, executed BEFORE the VM starts.

3. Remove the hard-coded templateDiskGB := 17 assumption.

4. Document the root-run template rebuild step (qm importdisk --size is additive per host, so template rebuild required).

Files changed

scripts/setup.sh (+TEMPLATE_DISK_SIZE option & qm importdisk --size)

cmd/create.go (absolute resize to VM_DISK_SIZE before start)

README.md (sizing behavior documented)

openspec/changes/template-disk-sizing/ (proposal, design, tasks, spec)

Verification (local)

go build ./... -> ok

go test ./cmd/... ./pkg/... -> ok

go fmt -l -> clean

bash -n scripts/setup.sh scripts/uninstall.sh -> ok

OpenSpec change validate -> valid (4/4 artifacts)

Confirmed open: live QEMU API verification

The template rebuild (qm importdisk --size) requires a live Proxmox host; this environment is not the Proxmox host. Once confirmed against the installed qm(1) that --size (MiB) is accepted, the task is complete on the live host.
